Name of Institute: Dr. D. Y. Patil College of Engineering and Innovation, Varale, Talegaon

Abstract:

This system presents an AI-driven job matching system designed to enhance the recruitment process for both job seekers and recruiters. Utilizing Python libraries such as Pandas, NumPy, OpenCV, and Scikit-learn, the application integrates face recognition and voice analysis to preprocess user datasets effectively. Job seekers input their skills, desired companies, job titles, interests, and notice periods, while the system generates personalized career guidance, including recommended courses, tutorials, and upskilling roadmaps. By scraping job insights directly from company career pages, the application offers users real-time information on available positions tailored to their qualifications. For recruiters, this tool streamlines talent acquisition by identifying the best-fit candidates from a pool of applicants. Overall, this system aims to facilitate meaningful connections between job seekers and employers, optimizing the job search and recruitment experience.

Keyword: Artificial Intelligence, CNN, Preprocessing, TF-IDF,

Mathematical Model / Algorithmic Representation:

1. **Term Frequency-Inverse Document Frequency (TF-IDF) for Job Matching:**

TF-IDF is a statistical measure used to evaluate how important a word is in a document relative to a collection of documents (corpus). In the context of job matching, TF-IDF converts textual data (such as job descriptions and candidate profiles) into numerical features, allowing the system to compare these documents effectively. It calculates the Term Frequency (TF) of each word, which represents how often the word appears in a document, and multiplies it by the Inverse Document Frequency (IDF), which reduces the importance of common words that appear frequently across all documents. This results in a feature set that emphasizes unique words in job descriptions or profiles, enabling efficient job matching.

$$D) = \log\left(\frac{N}{1 + |\{d \in D : t \in d\}|}\right)$$

- N: Total number of documents in the corpus DDD.
- |{d∈D:t∈d}| |\{d \in D : t \in d\}||{d∈D:t∈d}|: Number of documents containing the term ttt.
- +1+1+1 in the denominator avoids division by zero.

2. **Cosine Similarity for Matching Profiles with Job Descriptions:**

Cosine Similarity is a metric used to measure how similar two documents are, regardless of their size. It calculates the cosine of the angle between two vectors (which represent the documents in a high - dimensional space) to determine the similarity between them. In your project, Cosine Similarity is used to compare a candidate's profile vector (generated through TF-IDF) with job description vectors. A higher cosine similarity score indicates a better match between the candidate's qualifications and the job requirements, aiding in accurate job matching.

3. **Classification Algorithms for Job Role Prediction:**

Various Machine Learning Classification Algorithms are employed to predict suitable job roles based on a candidate's profile data. Some of the key algorithms include:

- **Logistic Regression:** A simple and widely used algorithm for binary classification. It predicts job roles based on the relationship between the features of the candidate's profile and the likelihood of each job role.
- **Random Forest:** A robust ensemble learning method that builds multiple decision trees and merges them to get more accurate and stable predictions. This is particularly useful for job role prediction, as it considers various factors like skills, experience, and certifications to classify candidates into suitable job roles.

4. **Face Encoding with HOG/CNN for Facial Recognition:**

Facial recognition in your system uses two key approaches:

- **Histogram of Oriented Gradients (HOG):** This method captures the structure and appearance of a face by focusing on the direction of intensity gradients.
- **Convolutional Neural Networks (CNN)**: A more advanced approach that uses deep learning to extract facial features. CNN-based face encoding analyzes the image through multiple layers of filters and convolutions, capturing complex patterns and structures for accurate facial recognition.

The face encoding creates a unique numerical representation of each face, which can then be compared to existing encoded faces in the database to identify users.

5. **Speech-to-Text Processing for Voice Recognition:**

Voice recognition in your system is implemented using speech-to-text processing. This involves converting the spoken voice input from users into text, which can then be processed to match against user profiles. Key steps in speech-to-text include:

- Acoustic Feature Extraction: Capturing audio signals and breaking them down into smaller units.
- Language Modeling: Predicting the likelihood of word sequences based on the given audio input.
- Matching Voice Input to Text Data: The system matches the converted text (spoken name, for instance) with user profiles for identification.

6. **Data Preprocessing:**

Preprocessing is a crucial step in ensuring that textual data is clean and ready for analysis. The key preprocessing steps include:

- **Tokenization:** Splitting the text into individual words or tokens.
- **Stop Word Removal:** Eliminating common words (such as "the", "is", "and") that do not contribute much to the meaning.
- **Lemmatization:** Reducing words to their base or root form (e.g., "running" becomes "run"), which helps in analyzing the data more effectively.
- **Stemming:** Text normalization technique in natural language processing (NLP) that reduces words to their root or base form by removing suffixes or prefixes (e.g., "running," "runner" → "run"). It helps in grouping related words and simplifying text for analysis.

Fig.1. System Architecture

1. **Start Process:** User/recruiter initiates the process via the UI-UX interface.
2. **User Workflow:**
   - **2.1 User Face Capture Login:** Login using facial recognition for user authentication and access.
   - **2.2 Select Option:** Update Search job/ Update job status.
   - **2.3 Search job:** AI model search job role for you and provide features based on your profile data which is stored in database and this all features are represented in UI.
     - **Eligible for job role:** AI MODEL analyses the user skill sets/user profile and suggest the jobs roles.
     - **New job roles and required skills:** AI models suggest new skills or certifications to users based on their interests.
     - **Vacancies and opportunities in companies:** If a user is searching for or eligible for a job role, the AI model suggests vacancies and opportunities in companies.

diately job joining opportunities: AI models suggest iate job openings in the market and opportunities for iate joining.

   - **2.4 Update job status:** here jobless, having a job and looking for a job etc, is job status of candidate and this data is stored in database.
3. **Recruiter Workflow:**
   - **3.1 Select option:** Update job opportunities/Hiring.
   - **3.2 Update job opportunities:** Vacancies or immediate job joining opportunity and this data is stored in database.
     - **Vacancies/Opportunity:** Recruiters upload job vacancies and joining opportunities, with all information securely stored in a database for easy retrieval
     - **Immediately Job Joining Opportunities:** Recruiters upload vacancy and immediate job joining opportunities, which are stored in a database for efficient access.
   - **3.3 Hiring:** Recruiter wants to hire some one.
   - **3.4 Face capture:** Here recruiter capture the face of candidate.
   - **3.5 AI model:** Start to recognize face of candidate.
   - **3.6 Face Recognition and Information Retrieval Model:** AI-powered job matching system that recognizes candidate faces and retrieves relevant information for streamlined hiring processes.
   - **3.7 Information processing model**: AI-powered job matching system that processes candidate information, providing recruiters with efficient and accurate hiring insights.
     - List of immediate joiner: AI models provide recruiters with a list of candidates available for immediate joining, with this status retrieved from the database.
     - Reading information: AI models retrieve and analyze candidate information from the database to provide recruiters with a list of individuals available for immediate joining.
     - Display information: AI models display key candidate information such as skills, experience, availability for immediate joining, location preferences, and qualifications, enabling recruiters to make informed hiring decisions.
     - Eligible for job role: AI models show a candidate's eligibility for job roles by displaying their skills, qualifications, work experience, certifications, and job preferences, helping match them to suitable positions.

Application:

1. Automates job matching for online recruitment platforms.
2. Facilitates global and remote work opportunities.
3. Identifies new job roles for individuals undergoing reskilling or upskilling.

Advantages:

1. Automates job matching, reducing time to hire.
2. Helps promote fair hiring by eliminating human biases.
3. Can handle large volumes of job seekers and job postings.
4. Matches candidates to jobs based on skills and qualifications.

Disadvantages:

1. Poor or incomplete data can result in inaccurate job matches.
2. Developing and implementing the system can be costly.

Conclusion:

AI-driven job matching and user identification systems offer significant potential to revolutionize the recruitment process. By leveraging advanced technologies such as natural language processing, machine learning, and computer vision, these systems can provide more accurate, efficient, and personalized recommendations for both job seekers and employers.
